

non

Why are linear inequalities so much harder to solve than linear ones?

1. linear graphs have no breaks or bends -
2. non-linear graphs bend & occasionally break (at asymptotes)

To solve these inequalities we find the breaks (set den = 0) & zeros (num = 0)

Solve  $1/x > 0$ .

step 1: set  $x=0$ .

step 2: test the inequality away from  $x=0$

$1/x \neq 0$  thus all  $x$  in this region will make the inequality fail

Solve  $(2+x)(1+x)(1-x) > 0$

step 1: solve  $2+x=0$ ,  $1+x=0$ ,  $1-x=0$

$x = -2$ ,  $x = -1$ ,  $x = 1$

step 2: test the inequality away from these points

**Solution**  
 $(-\infty, -2) \cup (-1, 1)$

$(2+0)(1+0)(1-0) > 0$   
 $(2-1.5)(1-1.5)(1-(-1.5)) \neq 0$

Example:  $\frac{x^2-1}{x^2-9} \leq 0$

Zeros:  $x^2-1=0$   
 $x = \pm 1$

**BREAKS**  $x^2-9=0$   
 $x = \pm 3$

\*For large numbers\*

**Solution**  
 $[-3, -1] \cup [1, 3]$
